

ROTARY SCREEN RS

Rotary screen is used for continuous separation of solid pollution in waste water. It can be equipped with additional integrated compactor.

Use Rotary screen is used in the different branches of the food-processing industry, especially in the meat-processing factories, slaughterhouses, dairy works, canning factories etc.

Generally, the rotary screen is installed before the flotation (DAF) as the first step of the waste water pre-treatment.

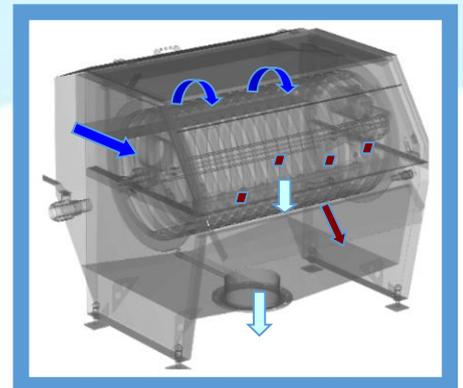

Rotary screen is used for continuous separation of solid pollution in waste water.

Principle of working Main operational part of rotary screen is a slot tube which is a welded structure with support profiles which are rods in the axial direction of the tube and surface profiles spirally wound around the support profiles.

Water is conveyed by a pump or flows by gravity on the slot tube and passes through the slots (slot sizes 0.25-2.50mm).

The solid pollution that exceeds the dimension of the slot, remains on the exterior of the rotating slot tube and it is scrapped and falls down into a container.

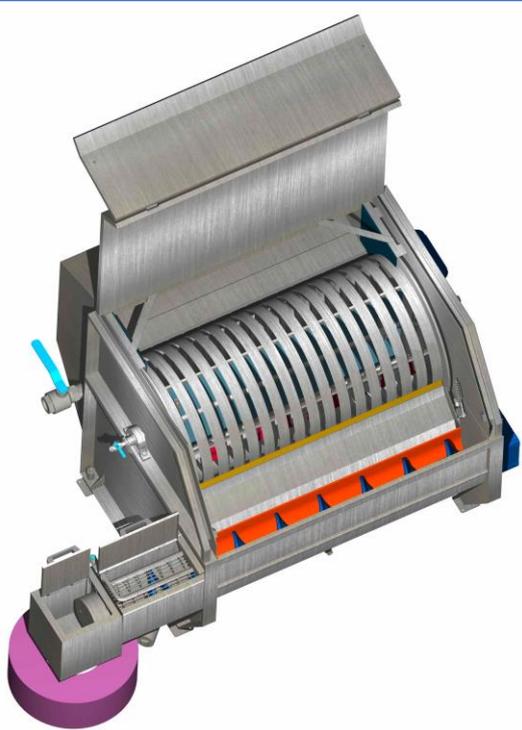

Treated water, free of solid pollution, flows out from the lower part of the rotary screen.

The inlet tank is equipped with an overflow draining away the excessive wastewater back to the pumping station.

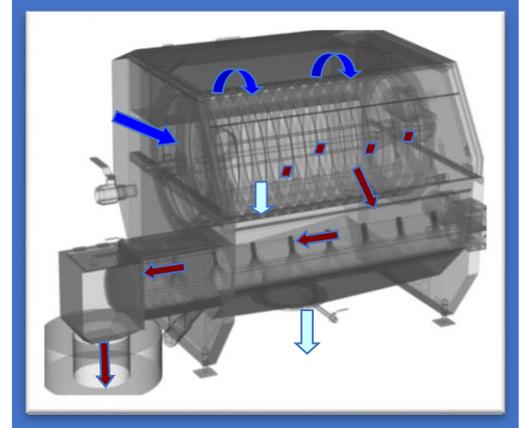

ROTARY SCREEN RC with integrated compactor

Rotary screen RC is based on the RS series but in addition has the integrated compactor.

Principle of working Screenings slide down into the skimmer and fall through the feeder into the rotating screw. The screenings move through the screw and are pressed towards the slotted screen. A thrust plate at the end of the screen exerts counter pressure needed to compact the screenings and dewater them as much as possible. While the thrust plate resistance is broken, the dewatered screenings fall into a container. Treated water, free of solid pollution, flows out from the lower part of the rotary screen. The water from screening goes directly to the outlet tank of the screen.

Rotary screen is not recommended for separation of fast settling contamination (gravel, metal particles, glass) and such other contamination which does not stick to the cylindrical screen and slides back into the inlet tank (pumice-stone, spherical impurities). For this use a VODATECH [drum screen](#) is recommended.

The overall output (m^3 of wastewater treated per hour) of the particular types of the RS/RC rotary screens always depends on the specific nature of the wastewater and on the specific conditions of the treatment, which should be consulted with the manufacturer.

ROTARY SCREEN RS/RC – Technical parameters
